Efficient server power supply by Dainard Jackson

Article published on November 25th 2011 | Business

Todayâ€™s modern server solutions are facing an uphill task in securing enough power supply for their sprawling needs. Many of them are constantly in situations of insufficient power capacity to meet their various demands. A reliable server power supply is only sufficient if it provides all the power needs not only for your latest editions of any server-related products but also for high-tech peripherals and computer software products.

No server can operate properly without adequate amounts of electricity. With more and more companies becoming aware of an approaching power constraint having already reached their limits, permanent solutions need to be used and made available to cater for these power needs.

Lack of innovative energy use, application management, and consolidation between procurement has greatly played a role in these power insufficiencies. Every server comes with different requirements for its power needs and so selecting the right server power supply goes a long way into maintaining efficiency.

The main logic and specification behind power supplies is how they use wattage to rate the current they use. Companies should ask themselves what type of power supply they need. An efficient supply ensures continuous power generation and protection and almost all types of servers rely heavily on power continuity so as to be fully functional in any business.

Efficient server power supply solutions focus on redundancy, availability, ease of servicing and resilience. All these can be achieved by investing in uninterruptable power supplies at the companies to act as the bridge between the mains power and standby power. Energy use also determines which type of power supply is needed.

Servers are critical loads that every company cannot function without and they therefore warrant sufficient power protection. Choosing the wrong solution may cause inefficiency in operations and thus the incurrence of extra costs that could be easily avoided. Reliable power supply systems from reputable companies in the industry consist of units offering an input power factor of not less than 99% therefore enabling companies to cut on energy wastage.

Every company knows that server loads are under constant change therefore meaning that they always have to be equipped to allow for future expansion of server power supply equipment. Modern technologies have allowed the integration of advanced onsite and remote monitoring capabilities within installed server solutions for better management. These power systems come with external or internal maintenance bypass which allows servicing without having the whole system being shut down thus ensuring productivity. However, to achieve better returns on these investments and increase their efficiency, proper and frequent maintenance must be carried out to prolong the supplyâ€™s productivity. Modern manufacturers are coming up with specific products to meet the rising needs and constraints of power supply solutions which are vital for every data center.
