Take an alcootest for a safe drive by Julia Bennet

Article published on February 4th 2012 | Society

Alcootest is a particular examination that determines the level of alcohol in your blood at a given time. This test is carried out through exhaling inside a pouch that measures the amount of alcohol present in the breath. Alcohol test is carried out in various ways through different devices, both manual and electronic. In different nations, the test is carried out through diverse methods. The most common tester used to diagnose the alcohol level in blood is a balloon that blows up. Ethylotest or breathalyzer is another commonly-used device that is used to estimate BAC or Blood Alcohol Content.

Ethylotest is the brand name used to market the device manufactured by National Draeger. There is a particular law enforcement grade of these devices, used only by the legal professionals to check if the drivers are permissible to be behind the wheel. It is an approved screening device that is widely used by the National Highway Traffic Safety Administration. Being one among the Conforming Products List, the item is used for both evidentiary and preliminary use. However, the manual alcootest device is a simpler version of the breathalyzer detector. Those taking the test requires to blow continuously into a balloon until it is fully inflated.

Then, the air inside the balloon is released into a glass test tube that is filled with yellow crystal bands. On passage of the air, if the color of the bands changes from yellow to green, then it means that the driver is influenced by alcohol. However, the legality of alcohol level in blood is determined by the law codes set by the state. If, you are to make use of an ethylotest, then you should scan through the instructions properly, in order to achieve accurate results. While taking the alcootest, read the instructions written at the back of the devices properly to learn the right method.

You need to wait up for 15 minutes after the consumption of alcohol to take the test. For smoke, a minute after the smoking is completed, is enough to diagnose the nicotine content in your blood. Some people are somehow apprehensive about how the alcootest feels. You can be rest assured that there will be absolutely no discomfort in taking the test. However, the point behind taking the test is to check if the driver is incapacitated to drive the vehicle safely. If the ethylotest gives out a result that is 0.03%, then you are certainly too high to be anywhere near a car.

If the result percentage touches 0.05%, it is medically said to be a state when muscle coordination in the body gets visibly reduced. Hence, time taken to respond, react or judge is exceedingly long and even the ability gets impaired. A normal and permissible percentage is when the level of alcohol in blood is not at all elevated.
